

# Design & Analysis of Algorithms

## Bucket Sort & Radix Sort

Prof. Wilson Rivera

Spring 2018

# Why might this help?

Implement the **buckets** as linked lists. They are first-in, first-out.

BucketSort:

Concatenate  
the buckets!

**SORTED!**

In time  $O(n)$ .

# Issues

- Need to be able to know what bucket to put something in.
  - That's okay for now: it's part of the model.
- Need to know what values might show up ahead of time.

2	12345	13	$2^{1000}$	50	100000000	1
---	-------	----	------------	----	-----------	---

# One solution: RadixSort

- **Idea:** BucketSort on the least-significant digit first, then the next least-significant, and so on.

Step 1: BucketSort on LSB:

## Step 2: BucketSort on the 2<sup>nd</sup> digit

## Step 3: BucketSort on the 3<sup>rd</sup> digit

It worked!!

# Why does this work?

Original array:

21	345	13	101	50	234	1
----	-----	----	-----	----	-----	---

Next array is sorted by the first digit.

50	21	101	1	13	234	345
----	----	-----	---	----	-----	-----

Next array is sorted by the first two digits.

101	01	13	21	234	345	50
-----	----	----	----	-----	-----	----

Next array is sorted by all three digits.

001	013	021	050	101	234	345
-----	-----	-----	-----	-----	-----	-----

Sorted array

# Correctness

- Argument via loop invariant (aka induction).
- Loop Invariant:
  - After the  $k$ 'th iteration, the array is sorted by the first  $k$  least-significant digits.
- Base case:
  - “Sorted by 0 least-significant digits” means not sorted.
- Inductive step:
  - (You fill in...)
  - This needs to use: (1) bucket sort works, and (2) we treat each bucket as a FIFO queue.
- Termination:
  - After the  $d$ 'th iteration, the array is sorted by the  $d$  least-significant digits. Aka, it's sorted.

# Running time

- Depends on how many digits the biggest number has.
  - Say  $d$ -digit numbers.
- There are  $d$  iterations
- Each iteration takes time  $O(n + 10)$ 
  - We can change the 10 into an “ $r$ ,” this is the “radix”
  - Example: if  $r = 2$ , we write everything in binary and only have two buckets.
  - Example: If  $r = 10000000$ , we write everything base-10000000 and have 10000000 buckets.
  - Example: if  $r = n$ , we write everything in base- $n$  and have  $n$  buckets.
- Time is  $O(d(n+r))$  .
- If  $d = O(1)$  and  $r = O(n)$ , running time  $O(n)$ .

So this is a  $O(n)$ -time sorting algorithm!

# Why would we ever use a comparison-based sorting algorithm?

- $d$  might not be “constant.” (aka, it might be big)

$\pi$	$\frac{123456}{987654}$	$e$	$140!$	$2.1234123$	$2^n$	$42$
-------	-------------------------	-----	--------	-------------	-------	------

- We can compare these pretty quickly (just look at the most-significant digit):
  - $\pi = 3.14\dots$
  - $e = 2.78\dots$
- But to do RadixSort we'd have to look at every digit.
- This is especially problematic since both of these have infinitely many digits...
- RadixSort needs extra memory for the buckets.
  - Not in-place
- I want to sort emoji by talking to a genie.
  - RadixSort makes more assumptions on the input.

# Summary

- How difficult a problem is depends on the model of computation.
- How reasonable a model of computation is is up for debate.
- RadixSort can sort smallish integers in  $O(n)$  time.
- If we want to sort emoji (or arbitrary-precision numbers), we require  $\Omega(n \log(n))$  time (like MergeSort).
